ABSTRACT

Beeswax is a valuable product that can provide a worthwhile income in addition to honey. One kilogram of beeswax is worth more than two folds of a kilogram of honey. In Ethiopia, beeswax is one of the important exportable agricultural commodities; the annual production of beeswax is estimated to be more than 5,000 tons. About 64,000 tons of beeswax were produced in the world, Asia (mainly India) being the major producer with 31,000 tons. Of all honey bee products the economic importance of beeswax is second after that of honey. Tropical countries dominate world beeswax production and export, with industrialized countries needing to import beeswax. Ethiopia is among the top four beeswax producers which is attributed to the predominantly traditional system of beekeeping production. The valuable beeswax resource is neglected in some areas of the tropics. Crude beeswax is collected from three sources. Of the total production the major part is utilized for the production of candle, and Twaf, a candle like stick that is used for church ceremony. Establishment of a beeswax collection and processing centre with the accessible rendering technologies and encouraging the beekeeper to handle the beeswax resource. Beeswax is relatively expensive, and there has always been a tendency for people to falsify or dilute with cheaper materials.

Keywords: Adulteration, Beeswax, Extraction, Rendering

INTRODUCTION

Beeswax is the creamy colored substance used by bees to build the comb that forms the structure of their nest. The comb provides the structure of the bees home, used for all the different storage functions needed in bees nest: to store honey, to store pollen, as a place to deposit eggs and for development of the young bees[1]. Beeswax is one of the most valuable and oldest bee products to be used by mankind [3,4,5]; and still being used in various fields of application such as cosmetics, foods, pharmaceuticals, engineering and industry [5]. Beeswax is a valuable product that can provide a worthwhile income in addition to honey. One kilogram of beeswax is worth more than one kilogram of honey. Beeswax as an income generating resource is neglected in some areas of the tropics. Some countries of Africa for example Ethiopia and Angola and in other developing countries where fixed comb beekeeping is still the norm, have significant production and export of beeswax, while in others the trade is neglected and beeswax is thrown away and often wasted [1]. Tropical countries dominate world beeswax production and export, with industrialized countries needing to import beeswax. Ethiopia is among the top four beeswax producers and this is considerably attributed to the predominantly traditional system of beekeeping production, which has relatively higher beeswax product per hive[5]. Worldwide, many honey hunters and beekeepers do not know that beeswax can be sold or used for locally made, high-value products. Knowledge about the value of beeswax and how to process it is often lacking. Even though it is impossible to give statistics, only half of the world production of beeswax comes on to the market, with the rest being thrown away and lost[1]. There are many market possibilities for good quality bees wax product in local emerging markets and to the foreign market and over 150 uses of beeswax were listed and described[6]. Beeswax is the second most valuable product after honey however many small scale traditional beekeepers throw away wax combs during harvesting or after honey extraction. Hence, it is important to build the knowledge and skills of the beekeepers and other value chain actors...
how to harvest, handle, process the beeswax and enhance awareness creation on its economical importance[7]. The natural composition of beeswax is a mixture of esters, fatty acids, higher alcohols and saturated hydrocarbons in addition to aromatic substances and pigments [2].

**IMPORTANCE OF BEESWAX**

**History of Beeswax Use**

Beeswax was mentioned in 32 prescriptions, given in a papyrus, compiled in Egypt about 1550 BC. It is praised for its beneficial influence on blood and energy systems and the overall balance of the body [8]. Candles of beeswax were used by the ancient Egyptians, ancient Greece, Rome and in old China. It was introduced in churches since the beginning of Christianity in Europe. In the world trade beeswax is used for the cosmetics industry, pharmaceutical industry, candle making, comb foundation sheet production and used for different other purposes among others polish, grafting waxes, lubricants, electronic insulations[1]. All the industries requires good quality natural beeswax wax. The average world price of beeswax usually around US$4-10 per kilogram. In industrialized countries, most nationally produced beeswax is used by the beekeepers for the production of comb foundation sheets.

**Beeswax Use at Present**

Now a day’s besides its use for comb foundations sheets to the improved beekeeping production, beeswax is used for following purposes : cosmetics 25-30, pharmacy 25-30 %, candles: 20 % and other purposes: 10-20 %. Beeswax is a very stable substance that resists oxidation. The composition of beeswax is very complex; the industry has not been able to produce a substitute with equal properties[8]. Although many synthetic waxes are available today, beeswax remains irreplaceable in many industrial applications [9,38]. The cosmetics and pharmaceutical industries have no complete substitute for beeswax. At least small quantities will always be needed to maintain quality and specific characteristics [10,38]. Beeswax candles are less common and more expensive than candles made from paraffin wax. In the past, church candles had to be made of 100 percent beeswax and this is still followed in some societies.

**Beeswax Production**

Bees need wax as construction material for their combs. The main raw materials for wax formation are carbohydrates, honey sugars fructose, glucose and sucrose[8]. Of all honey bee products the economic importance of beeswax is second after that of honey. It is estimated that its production is about 1.5 to 2.5 % of that of honey. The major world producer is China with an annual production of 6000 tons. About 64,000 tons of beeswax were produced in the world [11]. The raw products for wax manufacture are old combs and capping. Thus, all old combs and pieces of wax should be saved for rendering into wax blocks. Old combs should be rendered separately from newer ones since the newer combs yield a higher quality wax. The price for old combs depends on the age of combs: the darker the comb, the lower the wax recovery content and the lower price. Capping, containing almost exclusively pure wax, achieve the highest prices. Dark combs contain propolis and cocoons which lower the quality of the wax [8].

**Beeswax Production Potential in Ethiopia**

Small holder beekeepers are the primary sources of crude beeswax in Ethiopia. In addition, the local honey brewery industries for making Tej are the primary suppliers of bulk beeswax [20, 4]. Beeswax is collected in its segef (primary residue) from Tej left over and keskes (the partially extracted and molded one) [20, 3]. Ethiopia, having a huge apicultural resources, is the leading beeswax producer in Africa, and one of the important beeswax exporter to the world[29]. The average estimated annual beeswax production in Ethiopia for the last ten years is about 4,914 tons per year. The above estimate is without considering much of the beeswax produced in remote areas where it is usually wasted without harvest. Even though more wastage is estimated, in 2014 Ethiopia produced 5,344 tons of beeswax, which is 32.65% of the total beeswax produced in Africa (16,366 tons), 8.08% of the total beeswax produced globally (66,173 tons) [21]. Ethiopia is 4th in the world of raw beeswax production next to China, Mexico and Turkey[22]. The wax yield from traditional beehives is 8-10% of the honey yield, compared to 0.5-2% from modern hives. The bulk of the supply of beeswax obtained as residual from Tej production, a mild alcoholic beverage popular throughout Ethiopia [23,37]. The
majority of beekeepers in Ethiopia practice traditional beehives and hence, there is a potential to produce huge amount of beeswax [5]. The estimated beeswax production in Ethiopia is about 4300 tones this made Ethiopia stand first in Africa and third in the world. However, with the current increase in production of honey that is estimated to be around 54,000 tons the annual beeswax production is expected to be more than 5000 tones[21]. About 80% of the total Ethiopian honey production goes in to the local honey wine preparation called Tej [28]. It is an opportunity to make use of beeswax resource out of Tej leftover and to maximize the economical and social importance.

The Valuable Crude Bees Wax Resource loses

In many parts of the world much of the beeswax produced by bees that could be harvested by beekeepers is wasted. The beeswax is left or thrown away because beekeepers do not bother to collect, handle and render to make a marketable beeswax blocks[37]. As a result only a limited proportion, may be at most one-half, of the world's production of beeswax comes on to the market, the rest being thrown away or lost[4]. Beeswax resource as an income generating business is neglected in some areas of the tropics. Some countries of Africa where fixed comb beekeeping is still the norm, among others, Ethiopia and Angola, have significant export of beeswax, while in others the trade is neglected and beeswax is thrown away. Worldwide, many honey hunters and beekeepers do not know that beeswax can be sold or used for locally made, high-value products. Knowledge about the value of beeswax and how to process it is often lacking and the valuable beeswax is not properly harvested, collected and handled by the beekeepers and Tej house. Knowledge about the value of beeswax and how to process it is often lacking and the large amount of crude beeswax is wasted at the beekeepers back yard and Tej making house. The use of beeswax, the rendering techniques and even the existence of market demand for this product is not well known.

CRUDE BEESWAX RESOURCES AND OPPORTUNITIES FOR COLLECTION

There are three sources of beeswax one is from old combs and bits of brace comb gleaned from hives during manipulation[36]. The second source is from capping, at the time of honey extracting or processing the third and the major source in Ethiopian context is from the residue of Tej [14]. The smallholding beekeepers are the primary sources of beeswax in Ethiopia who sell the majority of crude honey to the Tej brewers. More of the marketable crude beeswax resource comes from Tej houses [5]. After the beverage production, the Tej makers collect the crude beeswax and store it as it is in the crude form Keskes or partially strained form of Keskes [31].Traditional beeswax extractors are also the other intermediate sources who process the Sefef the partially strained to rough beeswax blocks. The process by which wax from combs converted into blocks of clean wax is known as rendering [1].

Since whole combs are harvested and crushed or pressed, the proportion of wax per kilograms of honey (10-15%) is much higher than with frame hive, where the yield is only 1-2%[14]. Beeswax largely collected from traditional hives, the wax yield from traditional hives is 8-10% of the honey yield, compared to 0.5-2 % from modern hives. The bulk of the supply of beeswax obtained as residual from Tej production, a mild alcoholic beverage popular throughout Ethiopia [23]. Crude beeswax resource in Ethiopia is categorized from three sources, that are from Tej making, processed honey residue
and old and broken honey combs. The large proportion of crude beeswax resource for beeswax processors and exporter is from Tej residue house. Bees Wax resource obtained from honey capping during the honey harvest and processing are a source of the purest beeswax of high quality [15].

**Business Opportunities to Collect and Processing Beeswax**

Beeswax is a valuable commodity and export crop and can be used as the basis of many small business activities. A simple wax collecting system and bulk selling of beeswax can result in income from an otherwise wasted resource. The beekeepers, honey hunters and the local Tej makers should realize that beeswax is a valuable product. There are many market opportunities for good quality beeswax products in local emerging markets and in import substitution[5]. The production of bees wax in the European Union was 3,515 tons; an additional 6,335 tons of beeswax demand was from imported[10]. In Ethiopia of the total production of wax the major part is utilized for the production of candle, which is called tuwaf a a candle like sticks and used for church ceremony. Studies made by IPS some years back indicate that about 750 tons of bees wax is utilized for the production of tuwaf consumed mainly by about 25,000 Ethiopian Orthodox Churches. In addition more than 220 tons of wax is consumed by existing candle producing enterprises[5]. The exact data on the domestic production of beeswax are not available since it is produced at small-scale back yard, at forest beekeepers and at local Tej makers across all over the country. The Establishment of a beeswax collection and processing centre with the locally available rendering materials and technologies is the important and recommended business promotion and job opportunity creation strategies to the local community and to develop the economical benefit of the sub sector industry [16,10].

**Beeswax Rendering Technologies**

Industrial wax production began in the 19th century. In 1857 Mehring from Germany started industrial productions of comb foundations. World-wide, rendered beeswax is produced mainly by specialized beeswax manufacturers[33]. The process by which the crude beeswax converted into blocks of clean wax is known as rendering[7]. Before melting and processing the crude beeswax should be washed thoroughly to remove honey and other debris. Soaking in the water for several hours, or up to two days for older brood combs[17]. There are a number of different ways to process beeswax, all of which involve a combination of melting the beeswax and filtering. The hot mixture may then be squeezed out of the bag using two sticks. After melting the wax is not pure enough. For additional cleaning heat able water tanks from high grade steel are suitable. The wax should remain for longer time in the water bath at a temperature of 75-80°C (best over night)[8]. The wax recovery depends on the quality of the crude beeswax resource and on the method of rendering used. Generally, recovery from old combs are around 50%. If more capping and new combs are used it could be higher[1]. All methods of rendering involves melting the wax with water. The wax recovery depends on the combs and on the method used. Generally, recovery from old combs are around 50%. If more capping and new combs are used it could be higher[33]. Beeswax never be heated with a direct flame: always heat it in a container of water. This water bath might be an oil drum or other large container. Heat the wax enough to melt it: beeswax melts at 62-64°C. Heating above 85°C causes discoloration of the wax, and boiling will ruin it [1].

Direct exposure of wax to hot steam results in partial saponification and discoloration [8,18]. Beeswax may be heated in a double boiler or commercial wax melter following standard safety recommendations. The wax may be poured through a heavy fabric, like that of an old sweat shirt that is securely clipped or fastened over a container. The liquid wax may be poured through the simple filter to remove bits of dirt and hive contamination that naturally occurs in the hive. This process may need to be repeated more than once, depending on the use of the wax [19].

**Beeswax Quality Requirements**

Beeswax is valued according to its purity and sometimes its color - light wax (from new combs) is often more highly valued than dark wax (from old combs) [7,13]. The presence of pollen, propolis and impurities can cause the beeswax to become yellow [24, 25]. It will also darken with age so it is better used or sold as
quickly as possible. Beeswax is an extremely complex material containing over 300 different substances [26]. In addition, approx. 50 aroma components have been identified [27]. Pure beeswax has a good aroma, and when a wax block is broken, it shows a grainy surface. That is not the case if it has been adulterated with paraffin, fat or other oil. If pure beeswax is chewed, it does not stick to the teeth, and when rolled between fingers it softens but does not stick to the fingers. When paraffin wax is mixed with beeswax, it becomes more transparent and slightly greasy to the touch. The bright color of wax is more appreciated than dark-colored wax [24]. The composition of beeswax depends on the content of paraffin hydrocarbons, free fatty acids, esters of fatty acids and fatty alcohols [26]. Presently, because of its high demand and shortage in the world market, its adulteration with cheaper materials became a challenge for its quality and marketing. On the other hand the deterioration of beeswax's natural quality and the alteration of its composition as a result of prolonged over heating during rendering have been reported [27,13]. The authenticity of beeswax can be determined by using physical-chemical parameters, such as melting point, density, acid value, saponification value, ration number, ester value, iodine absorption number, and peroxide value [24,40].

Color does not affect the quality of the wax, unless it is dark from over-heating. Under local conditions deterioration of beeswax quality due to overheating from processing is highly likely to happen; some of the processing facilities are not suitable to regulate the optimum temperature during processing [10]. Even though, Ethiopia has developed the beeswax quality standards, setting marketing and quality regulation legal frame work and assigning the relevant administration and regulatory body is still on process. Longer heating or higher temperatures lead to greater quality degradation and loss of hydrocarbons [26]. In industrialized countries, the widespread use of chemicals in beekeeping and subsequent contamination of beeswax makes the beeswax harvested from disease-free colonies in Africa and other regions more precious and valuable[39].

The main quality issues concern authenticity of origin, and contamination from residues of drugs used to control honeybee diseases, mainly the acaricides used to control mite predators. These acaricides are lipophilic and therefore are soluble in beeswax, and accumulate in it. The contamination of beeswax can be minimized by avoiding the use of chemicals in beekeeping. The use of these chemicals in beekeeping in industrialized countries makes beeswax harvested from the disease-free colonies of Africa and other developing regions more attractive [1].

**Adulteration**

Beeswax is relatively expensive, and there has always been a tendency for people to try to falsify or dilute it with cheaper materials. The melting point of pure beeswax is 64.5° C, and adulteration of pure beeswax with paraffin wax reduces the melting point and weakens the material[1]. The adulteration of beeswax with cheaper materials like animal fats, plant oils and paraffin has become a national and international problem. It has a great influence on quality assurance and its marketing[5]. To detect adulteration, a number of tests may have to be conducted. The simplest test is to determine the melting point by measuring the temperature at which the first liquid wax appears during very slow heating. It should be between 61 and 66°C or preferably between 62 and 65°C [10]. Beeswax samples adulterated with 1% animal tallow melted at slightly lower temperature at an average of 61oC, which was lower by 1oC than the lower limit of most pure beeswax melting point standards [5]. Adulteration with paraffin wax depresses the melting point (64.5°C) and weakens the material. It follows that using adulterated wax for foundation will weaken the comb and cause problems for the bees and the beekeeper.

**Physical Characteristics of Beeswax**

Newly produced wax in the hives is clear white, but after manipulation by the bees, it soon turns pale yellow. New honeycomb is nearly white and if it is only used for honey storing it will retain its light color. The coloration of beeswax, shades of yellow, orange and red through to brown is due to the presence of various substances, especially pollen. This difference in color is of no significance as far as the quality of the wax is concerned, but subjectively light colored wax is more highly valued than dark colored wax [5]. The structure of beeswax is
crystalline and the crystallization process increases upon storage of wax until 3-4 months, while at the same time, its stiffness and elasticity increase[12]. Beeswax is a very stable substance, resistant to natural oxidation and insoluble in water. It is a complex material with a characteristic odor mainly derived from the bees themselves and honey, pollen or propolis. Wax is solid at room temperature and becomes brittle below 18°C. It is soft and pliable around 35-40°C, and melts at 64.5°C [32].

**Composition and Properties**

Beeswax is a very stable substance, and its properties change little over time. It is resistant to hydrolysis and natural oxidation and is insoluble in water. It is a complex material consisting of many different substances, but predominantly of esters of higher fatty acids and alcohols, pigments mostly from pollen and propolis, as well as minute traces of bee material[30,31]. It is solid at room temperature, becomes brittle once the temperature drops below 18°C and quickly becomes soft and pliable at around 35 to 40°C, with a melting point of 64.5°C C[1]. Beeswax naturally composed of carbon, hydrogen, and oxygen and has a long carbon chains of fatty acid esters and aliphatic alcohols [19,36]. Beeswax is an inert material with high plasticity at a relatively low temperature (around 32 °C). Upon heating the physical properties of wax changed. At 30-35°C it becomes plastic, at 46-47°C the structure of a hard body is destroyed and between 60 to 70°C it begins to melt. Heating to 95-105 °C leads to formation of surface foam, while at 140°C the volatile fractions begin to evaporate [33]. The melting point of beeswax is not constant since the composition varies slightly with its origin. Various pharmacopoeias give a range of 61-66°C or more commonly, 62-65°C[19,30]. The saponification value of beeswax is 85-100°C it is also insoluble in water, soluble in most organic solvents and resistant to many acids[12,31].

**Market Demand**

The world production of around 60,000 metric tons of beeswax has multiple uses. The EU imports around 6,000 tons of beeswax per annum, approximately 50 percent of this coming from developing countries. Tropical countries dominate world beeswax production and export, with industrialized countries needing to import beeswax[1,36]. Because of its high demand and shortage in the world market, adulteration of beeswax with cheaper materials has been a challenge to sustain in the existing market and to access new market.

**Beeswax Marketing and Trade in Ethiopia**

Beeswax is one of the primary exportable agricultural products of Ethiopia [21]. The country has been well known in beeswax trade for a long time and is one of the four biggest wax exporters to the world market amounting to on average about 347tons per year in increasing trend from time to time. This demonstrates that less than 10% of the total estimated beeswax production of the country is exported. The remaining larger portion of it is either used in local market and or wasted[22]. Beeswax Exports from Ethiopia have increased and reached 402 tons (1.2% share in world market), destination to different countries (USA, Japan, Greece, Great Britain and Netherlands etc.) [5]. Export of bees wax for the last 7 years (2011-2017) is summarized in figure 1.

The estimated annual production of beeswax is to be about 5000 tons. It indicated that around one tenth of the world annual beeswax production that is estimated to be around 50,000 tons. Beeswax from Ethiopia has higher demand and also earns higher price in EU, that is mainly used for blending low quality beeswax from different sources[5]. The crude beeswax resource marketing and supply system is a pattern of fragmented distribution channels and supply chain, it cause a significant challenge to traceability. Beeswax has market demand in Ethiopia. The religious practice of the Ethiopian Orthodox Church followers to burn candle sticks called tuwaf and foundation sheet production to the improved beekeeping are consume certain amount of the beeswax[5]. In the domestic market, farmers either sell directly or through middlemen, collectors and suppliers [13].

The average annual beeswax export from Ethiopia to different destination countries was about 365tons. Based on the CSA 2017/2018 data Ethiopia produce about 47,710 tons of crude honey the estimated beeswax product with the proportion 8 percent could be about 3816.8 tons. On the same year Ethiopia export about
A Review on Crude Beeswax Mismanagement and Lose: Opportunities for Collection, Processing and Marketing in Ethiopia

302.34 tons of beeswax which is about 8 percent of the total production. Even though, it is difficult to have the exact data of beeswax consumption locally to Candle and (Tuwaf) making, and to make foundation sheets to the improved beekeeping, lose of more beeswax is indicated.

![Figure 1. Beeswax export performance from Ethiopia for the years (2011-2017)](image)

**CONCLUSION**

Beeswax is one of the important exportable agricultural commodities in the international market. Because of its pliability, yellow coloration and other physical properties, the Ethiopian beeswax has been highly demanded and mostly used to blend beeswaxes from other sources. Despite Ethiopia has huge potential for production of high quality beeswax, only less than 10% of the beeswax produced is exported. Beeswax as an income generating resource is neglected in some areas of the tropics. Some countries of Africa where fixed comb beekeeping is still the norm, for example, Ethiopia and Angola, have significant export of beeswax, while in others the trade is neglected and beeswax is thrown away. Knowledge about the value of beeswax and how to process it is often lacking. Due to this large amount of crude beeswax is wasted at the beekeepers back yard and Tej making houses. Awareness creation on the economical value and importance of the beeswax, developing the knowledge and skills on the handling and rendering techniques and communicating the existence of market demand for this product along all the value chain is important. Similarly, Introduction and adoption improved processing techniques and technologies of higher efficiency is to be important interventions to be taken to increase the production and productivity of the beeswax. Establishment of beeswax collection center and set the marketing legal framework that have clear path of the products movements in the market is important to assure the quality, to minimizes the problem of adulteration to develop traceability system.

**RECOMMENDATIONS**

Developing the knowledge and skills of the beekeepers, the local Teji makers and all other value chain actors on the valuable beeswax resource collecting, handling, processing, quality assurance and marketing are the areas needs stringent attention and intervention strategies.

Establishment of the beeswax collection and processing centers in particular at beeswax resources potential areas of the country and developing awareness creation on the economical importance of valuable beeswax resource is the important and recommended business promotion and job opportunity creation strategies to the local community and to enhance the economical benefit of the sub sector industry.

Put in place and functionalize the quality administration, quality control and market chain system regulation and set up a clear path of the products movements in the market chain. It is
important to produce traceable products and reduce the problem of adulteration hence, the country be able to boost beeswax export market.
